# What is Machine Learning

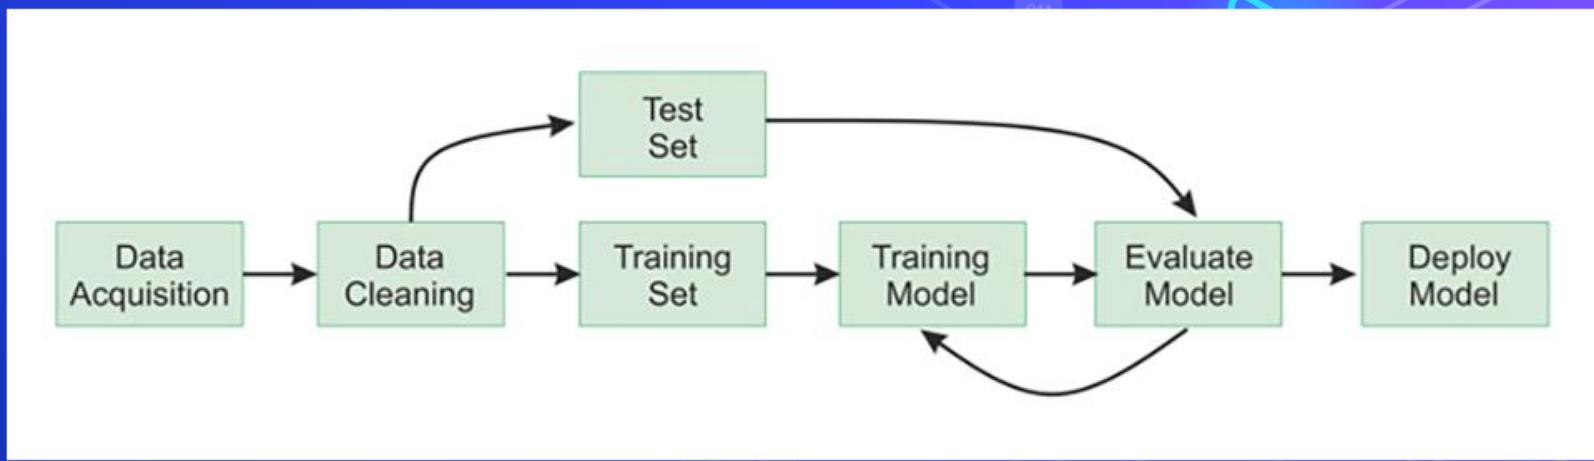

Machine learning involves computers discovering how they can perform tasks without being explicitly programmed to do so. It involves computers learning from data provided so that they carry out certain tasks.

# What is Machine Learning

# What is Machine Learning

# What is Machine Learning

## Classical Machine Learning

Task Driven

### Supervised Learning

( Pre Categorized Data )

#### Classification

( Divide the socks by Color )

Eg. Identity Fraud Detection

#### Regression

( Divide the Ties by Length )

Eg. Market Forecasting

Data Driven

### Unsupervised Learning

( Unlabelled Data )

#### Clustering

( Divide by Similarity )

Eg. Targeted Marketing

#### Association

( Identify Sequences )

Eg. Customer Recommendation

#### Dimensionality Reduction

( Wider Dependencies )

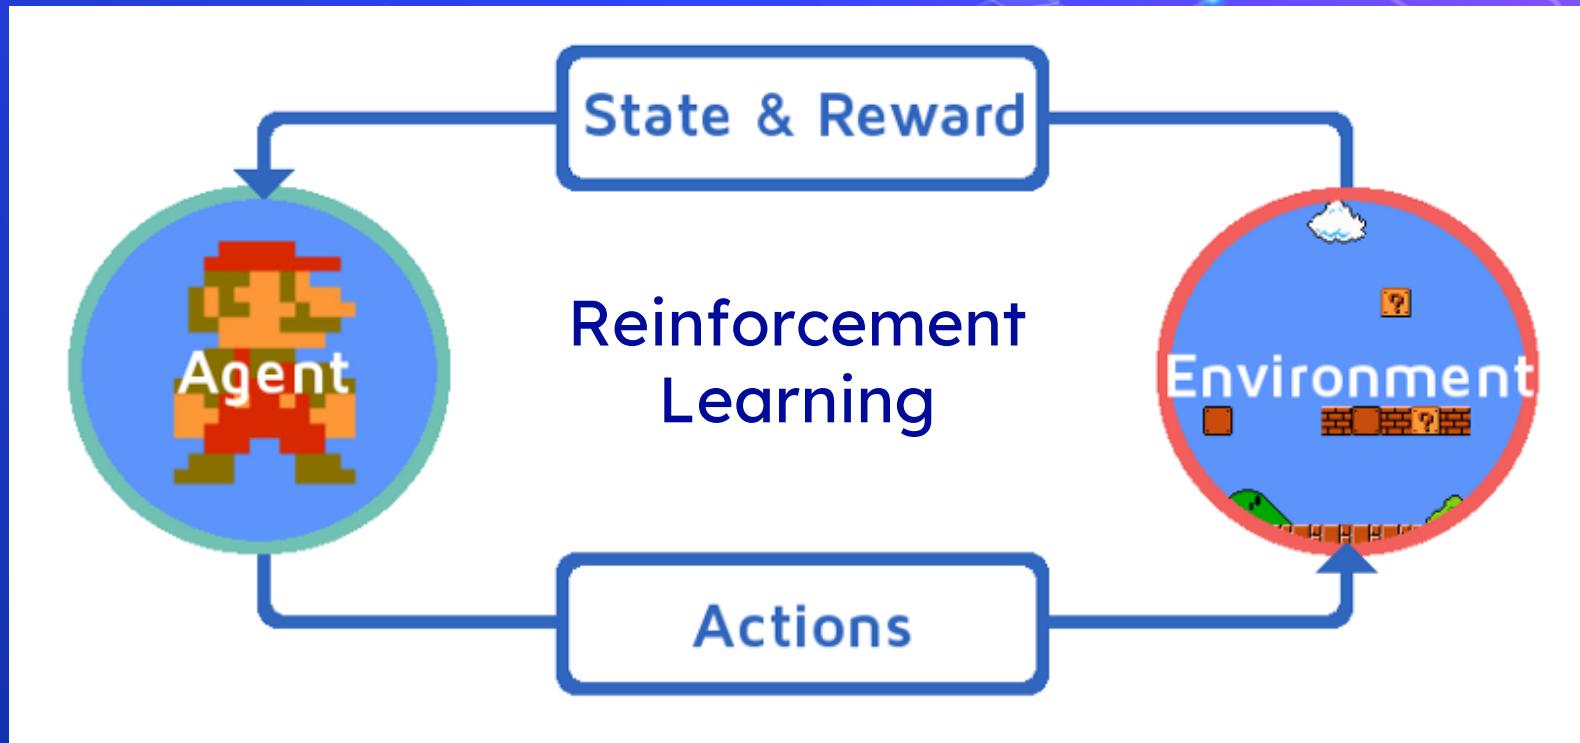

Eg. Big Data Visualization

Obj: Predictions & Predictive Models

Pattern/ Structure Recognition

# What is Machine Learning

# What is Machine Learning

- Supervised learning : Task Driven (Classification, Regression)
- Unsupervised learning : Data Driven (Clustering)
- Reinforcement learning :
  - Close to human learning.
  - Algorithm learns a policy of how to act in a given environment.
  - Every action has some impact in the environment, and the environment provides rewards that guides the learning algorithm.

# Agenda

  - Dimension Reduction
- Model Selection & Evaluation
  - Cross Validation
  - Hyperparameter Tuning
- Intro to Deep Learning

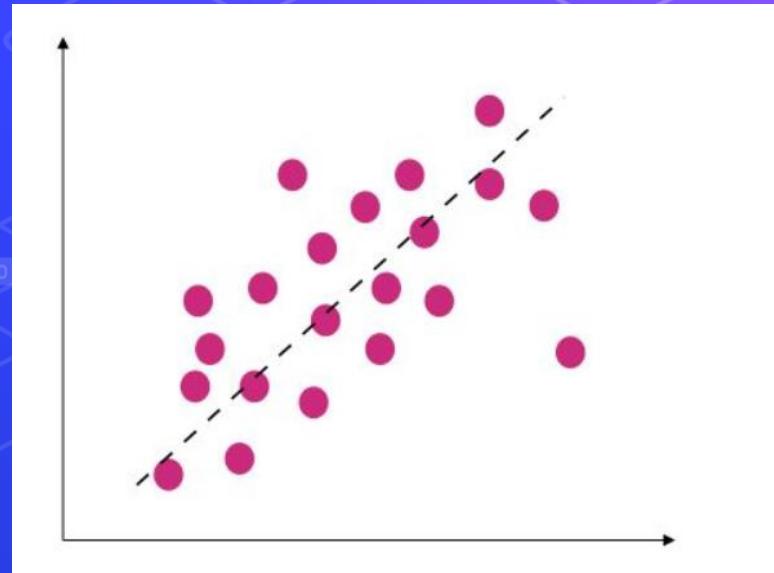

# Regression

Regression quantifies the relationship between one or more predictor variable(s) and one outcome variable.

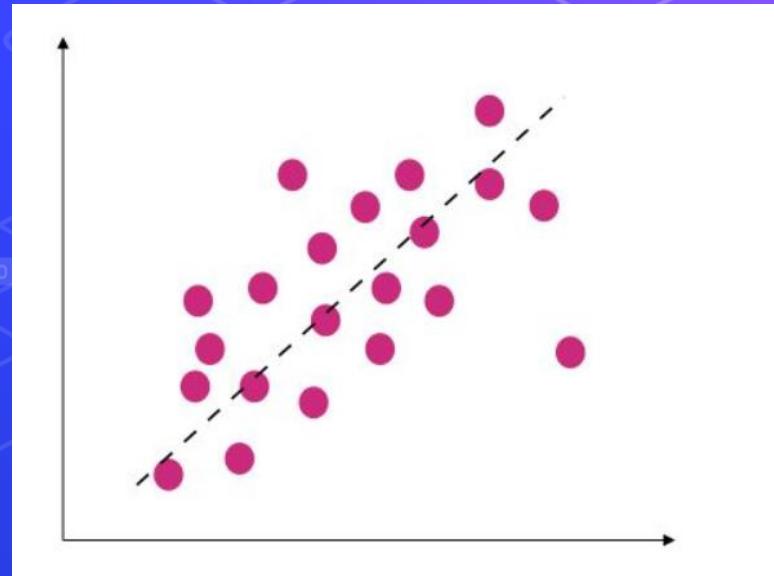

For example,  
it can be used to quantify the relative impacts of age, gender,  
and diet (the predictors) on weight (the output or dependent).

- House prices based on size, locations,...
- Salary prediction based on experience
- Stock Market prediction
- Weather prediction
- ...

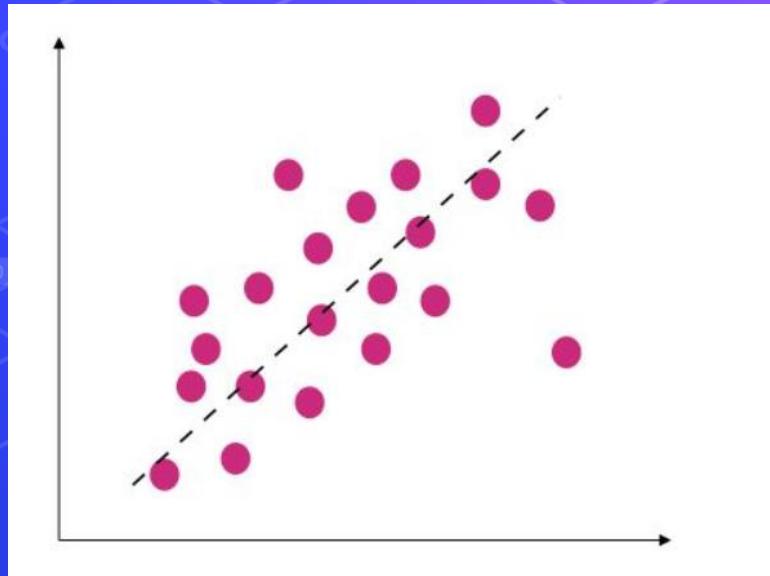

# Regression

# Simple Linear Regression (Equation of a straight line)

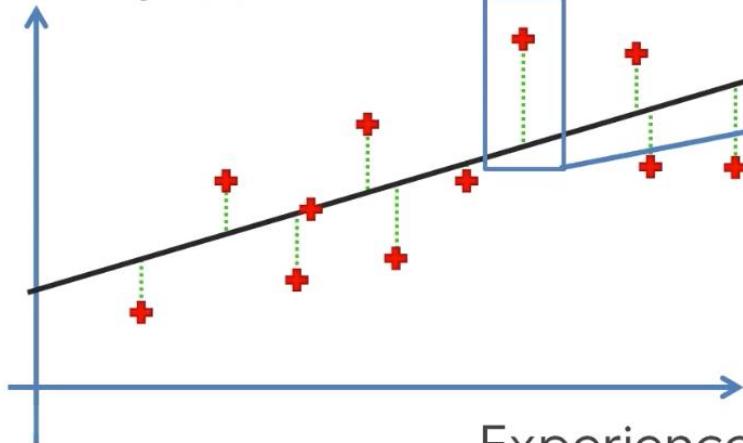

It also called ordinary least squares (OLS)

# Simple Linear Regression (Calculate Cost Function)

Simple Linear Regression:

Salary (\$)

$y_i$

$\hat{y}_i$

Hypothesis: 
$$h_{\theta}(x) = \theta_0 + \theta_1 x$$

Parameters:  $\theta_0, \theta_1$

Cost Function: 
$$J(\theta_0, \theta_1) = \frac{1}{2m} \sum_{i=1}^m (h_{\theta}(x^{(i)}) - y^{(i)})^2$$

Goal: 
$$\underset{\theta_0, \theta_1}{\text{minimize}} J(\theta_0, \theta_1)$$

# Simple Linear Regression (Calculate Cost Function)

The goal is to minimize the sum of squares of residuals ( $y - y'$ ) is as small as possible.

Hypothesis:  $h_{\theta}(x) = \theta_0 + \theta_1 x$

Parameters:  $\theta_0, \theta_1$

Cost Function:  $J(\theta_0, \theta_1) = \frac{1}{2m} \sum_{i=1}^m (h_{\theta}(x^{(i)}) - y^{(i)})^2$

Goal:  $\underset{\theta_0, \theta_1}{\text{minimize}} J(\theta_0, \theta_1)$

# Simple Linear Regression (Example)

Theta0 = 5 , theta 1 = 2

Equation  $h(x) = 5 + 2x$

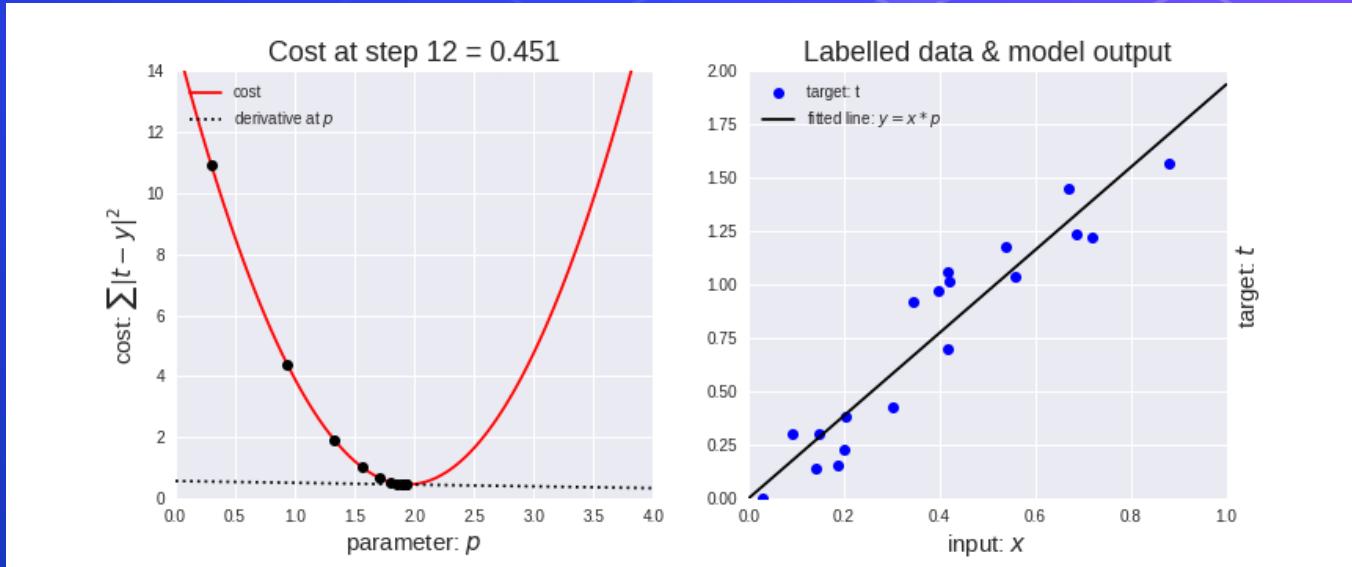

X	Y	$h(x)$	$h(x) - y$	$(h(x) - y)^2$
1	7	7	0	0
2	8	9	1	1
2	7	9	2	4
3	9	11	2	4
4	11	13	2	4
5	10	15	5	25
5	12	15	3	9

$$J(\theta_0, \theta_1) = \frac{1}{2m} \sum_{i=1}^m (h_\theta(x^{(i)}) - y^{(i)})^2$$

$$J = 1 / 14 ( 0+1+4+4+4+25+9 )$$

$$J = 47/14 = 3.3$$

# Simple Linear Regression (Minimize cost using Gradient Descent)

repeat until convergence:

$$\theta_j := \theta_j - \alpha \frac{\partial}{\partial \theta_j} J(\theta_0, \theta_1)$$

$$\theta_0 := \theta_0 - \alpha \frac{1}{m} \sum_{i=1}^m (h_\theta(x_i) - y_i)$$

$$\theta_1 := \theta_1 - \alpha \frac{1}{m} \sum_{i=1}^m ((h_\theta(x_i) - y_i)x_i)$$

# Simple Linear Regression (Minimize cost using Gradient Descent)

## Cost Function

$$J(\Theta_0, \Theta_1) = \frac{1}{2m} \sum_{i=1}^m [h_\Theta(x_i) - y_i]^2$$

↑  
Predicted Value      ↑  
True Value

## Gradient Descent

$$\Theta_j = \Theta_j - \alpha \frac{\partial}{\partial \Theta_j} J(\Theta_0, \Theta_1)$$

↑  
Learning Rate

NOW,

$$\begin{aligned}\frac{\partial}{\partial \Theta} J_\Theta &= \frac{\partial}{\partial \Theta} \frac{1}{2m} \sum_{i=1}^m [h_\Theta(x_i) - y_i]^2 \\&= \frac{1}{m} \sum_{i=1}^m (h_\Theta(x_i) - y) \frac{\partial}{\partial \Theta_j} (\Theta x_i - y) \\&= \frac{1}{m} (h_\Theta(x_i) - y) x_i\end{aligned}$$

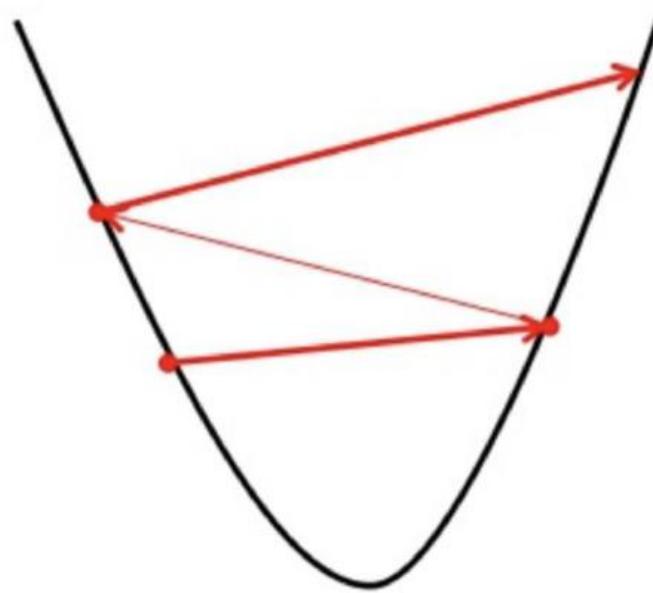

Therefore,

$$\Theta_j := \Theta_j - \frac{\alpha}{m} \sum_{i=1}^m [(h_\Theta(x_i) - y) x_i]$$

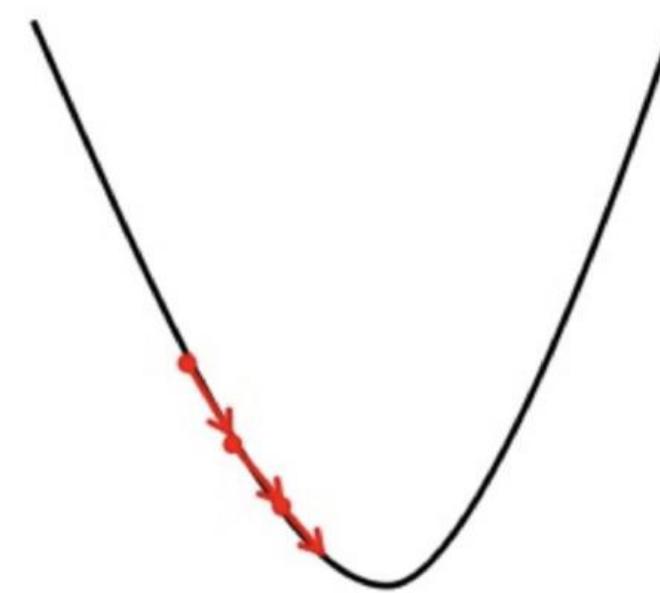

# Simple Linear Regression (Alpha constant)

Big learning rate

Small learning rate

# Multiple Linear Regression (Equation)

Simple

# Other Regression Algorithms

- K-Nearest Neighbors (KNN)
- SVM
- Decision Trees
- Random Forests
- XGBoost

# Underfitting & Overfitting

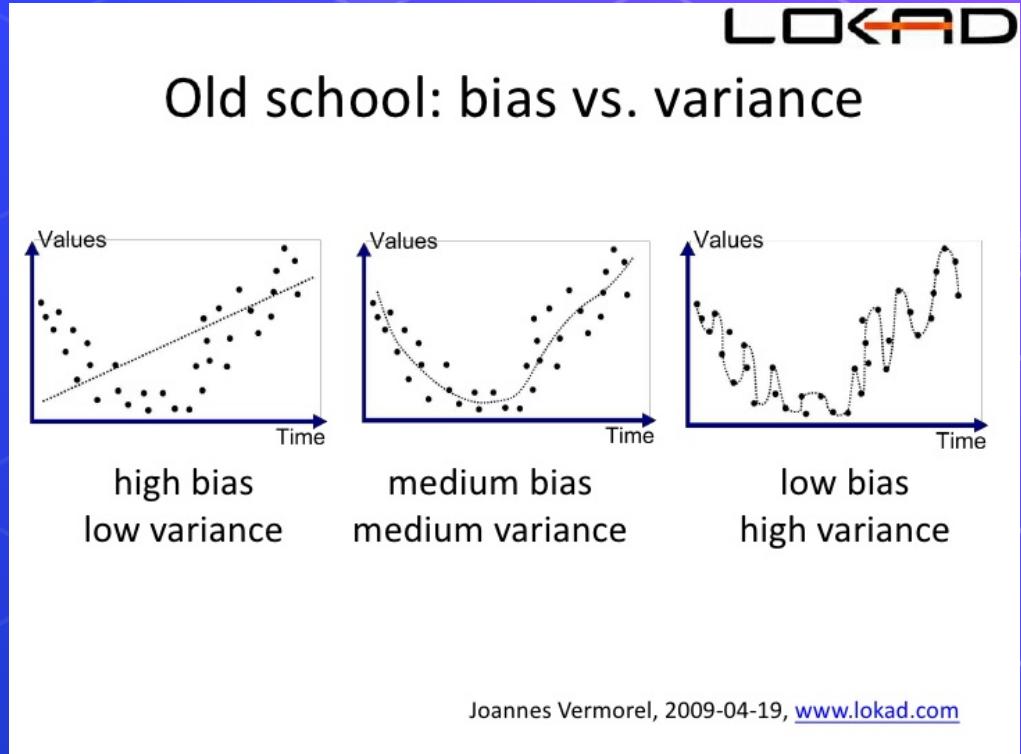

# Underfitting & Overfitting

The more features you add the accuracy improves but this can lead to **Overfitting** that means the model memorizes the data too much and not applying **Generalization**.

So we should know about the trade-off between **Bias** and **Variance**.

- A model with a high bias error underfits data and makes very simplistic assumptions on it.
- A model with a high variance error overfits the data and learns too much from it.
- A good model is where both Bias and Variance errors are balanced

# Underfitting & Overfitting

## Underfitting (High Bias, Low Variance)

Model is so simple and weak to understand and represent data.

High Train Error + High Test Error

## Overfitting (Low Bias, High Variance)

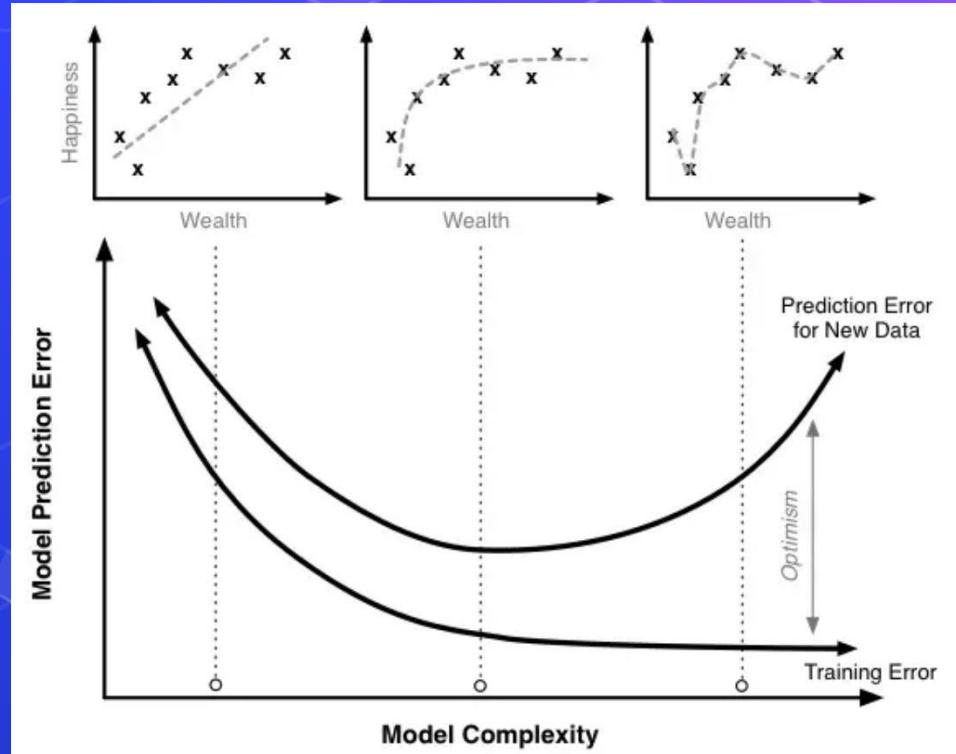

Model is so complex so it memorizes training data and can't apply generalization.

Low Train Error + High Test Error

## Optimal (Low Bias, Low Variance)

Model is not simple nor complex and apply generalization well.

Low Train Error + Low Test Error

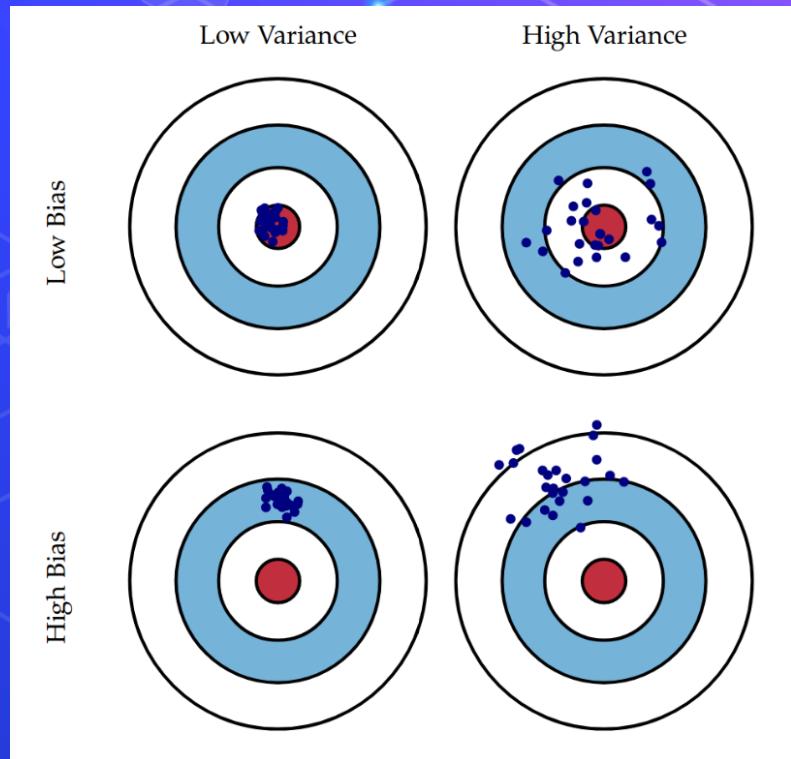

# Underfitting & Overfitting

## Techniques to reduce underfitting

- Increase model complexity.
- Increase number of features.
- Performing feature engineering.
- Remove noise from the data.

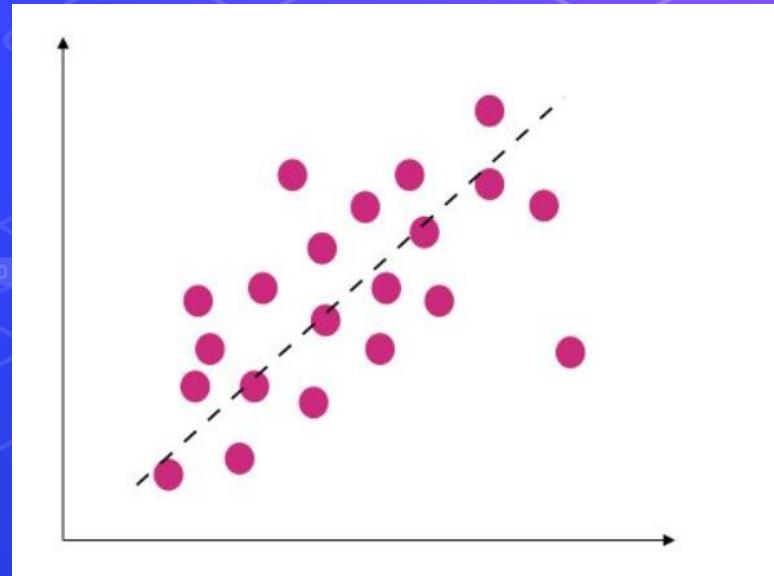

## Techniques to reduce overfitting

- Increase training data.
- Remove correlated features.
- Use simpler model.
- Regularization (add penalty bias).

# Classification

Classification specifies the class to which data elements belong to and is best used when the output has finite and discrete values. It predicts a class for an input variable as well.

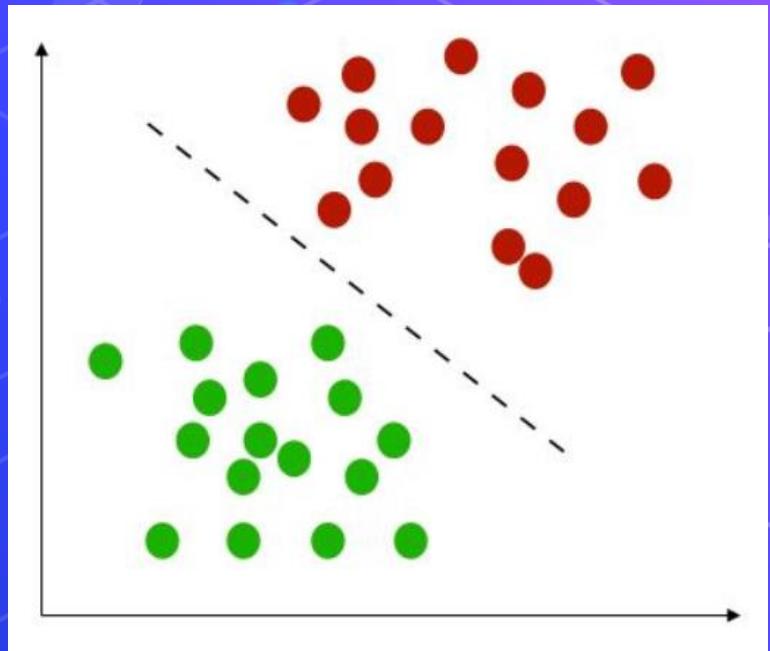

For example,  
it can be used to classify the animal in an image, it's either a cat or a dog.

  - Random Forests
  - XGBoost
- Evaluating Model Performance

# Evaluating Model Performance (Confusion Matrix)

		Actual Value	
		Positive	Negative
Predicted Value	Positive	TP (True Positive)	FP (False Positive)
	Negative	FN (False Negative)	TN (True Negative)

- True Positive (TP) : Observation is positive, and is predicted to be positive.
- False Negative (FN) : Observation is positive, but is predicted negative.
- True Negative (TN) : Observation is negative, and is predicted to be negative.
- False Positive (FP) : Observation is negative, but is predicted positive.

# Evaluating Model Performance (Confusion Matrix)

**True positives (TP):** actuals are positives and are predicted as positives.

*You predicted that a woman is pregnant and she actually is.*

**False positives (FP)** - Type 1 Error: actuals are negatives and are predicted as positives.

*You predicted that a man is pregnant but he actually is not.*

**False negatives (FN)** - Type 2 Error: actuals are positives and are predicted as negatives.

*You predicted that a woman is not pregnant but she actually is.*

**True negatives (TN):** actuals are negatives and are predicted as positives.

*You predicted that a man is not pregnant and he actually is not.*

# Evaluating Model Performance (Confusion Matrix)

```
1 from sklearn.metrics import confusion_matrix  
2  
3  
4 confusion_matrix(y_pred, y_true)  
5  
6 """  
7 array([[43,  2],  
8        [11, 87]], dtype=int64)  
9 """
```

# Evaluating Model Performance (Accuracy)

## Accuracy

---

- It's a measure of how good the model is.
- It's the ratio of the true predicted values over all the values.

Accuracy:

$$ACC = \frac{TP + TN}{TP + TN + FP + FN}$$

Recall:

$$Recall = \frac{TP}{TP + FN}$$

Precision:

$$Precision = \frac{TP}{TP + FP}$$

F<sub>1</sub> score:

$$F_1 = \frac{2}{\frac{1}{Recall} + \frac{1}{Precision}}$$

# Evaluating Model Performance (Accuracy)

```
1 from sklearn.metrics import accuracy_score  
2  
3  
4 accuracy_score(y_pred, y_true)  
5  
6 """  
7 0.9090909090909091  
8 """
```

# Evaluating Model Performance (Recall or Sensitivity)

- TP will be that the COVID 19 residents diagnosed with COVID-19.
- TN will be that healthy residents are with good health.
- FP will be that those actually healthy residents are predicted as COVID 19 residents.
- FN will be that those actual COVID 19 residents are predicted as the healthy residents.

which scenario do you think will have the highest cost?

Imagine that if we predict COVID-19 residents as healthy patients and they do not need to quarantine, there would be a massive number of COVID-19 infections. The cost of false negatives is much higher than the cost of false positives.

**Case 1**

COVID 19 = 1  
Healthy = 0

Cost of FN > Cost of FP

Actual

Healthy predicted as sick

Sick predicted as healthy

Predict	COVID 19 (1)	Diagnosed COVID 19 (1)	Diagnosed Healthy (0)
Covid 19 (1)	TP	FP	
Healthy (0)	FN	TN	

# Evaluating Model Performance (Recall or Sensitivity)

## Recall (Sensitivity)

- It's a ratio of True Positives to all the positives in your data.
- Low recall: the more False Negatives the model predicts, the lower the recall.

$$\text{Recall} = \frac{\text{True Positive}}{\text{Predicted Results}} \quad \text{or} \quad \frac{\text{True Positive}}{\text{True Positive} + \text{False Negative}}$$

Accuracy:

$$ACC = \frac{TP + TN}{TP + TN + FP + FN}$$

Recall:

$$\text{Recall} = \frac{TP}{TP + FN}$$

Precision:

$$\text{Precision} = \frac{TP}{TP + FP}$$

F<sub>1</sub> score:

$$F_1 = \frac{2}{\frac{1}{\text{Recall}} + \frac{1}{\text{Precision}}}$$

# Evaluating Model Performance (Recall or Sensitivity)

```
1 from sklearn.metrics import recall_score  
2  
3  
4 recall_score(y_pred, y_true)  
5  
6 """  
7 0.9090909090909091  
8 """
```

# Evaluating Model Performance (Precision)

- TP will be that spam emails are placed in the spam folder.
- TN will be that important emails are received.
- FP will be that important emails are placed in the spam folder.
- FN will be that spam emails are received.

which scenario do you think will have the highest cost?

Well, since missing important emails will clearly be more of a problem than receiving spam, we can say that in this case, FP will have a higher cost than FN.

**Case 2**

Spam = 1  
Not Spam = 0

Cost of FP > Cost of FN

Actual

Not spam predicted as spam

Predict

	Spam (1)	Not Spam (0)
Spam (1)	TP	FP
Not Spam (0)	FN	TN

Spam predicted as not spam

# Evaluating Model Performance (Precision)

## Precision

- It's a ratio of True Positives to all the positives predicted by the model.
- Low precision: the more False positives the model predicts, the lower the precision.

$$\text{Precision} = \frac{\text{True Positive}}{\text{Actual Results}} \quad \text{or} \quad \frac{\text{True Positive}}{\text{True Positive} + \text{False Positive}}$$

Accuracy:

$$ACC = \frac{TP + TN}{TP + TN + FP + FN}$$

Recall:

$$\text{Recall} = \frac{TP}{TP + FN}$$

Precision:

$$\text{Precision} = \frac{TP}{TP + FP}$$

F<sub>1</sub> score:

$$F_1 = \frac{2}{\frac{1}{\text{Recall}} + \frac{1}{\text{Precision}}}$$

# Evaluating Model Performance (Precision)

```
1 from sklearn.metrics import precision_score  
2  
3  
4 precision_score(y_pred, y_true)  
5  
6 """  
7 0.9090909090909091  
8 """
```

# Evaluating Model Performance

Case 1

COVID 19/ Healthy

Case 2

Spam/Not Spam

Cost of **FN** > Cost of **FP**

Cost of **FP** > Cost of **FN**

Recall

$$\text{recall} = \frac{\text{true positives}}{\text{true positives} + \text{false negatives}}$$

Precision

$$\text{precision} = \frac{\text{true positives}}{\text{true positives} + \text{false positives}}$$

# Evaluating Model Performance (F-1 Score)

## F-1 Score

- F-Score called the Harmonic mean of precision and recall.
- F-Score provides a single score that balances both the concerns of precision and recall in one number.
- A good F1 score means that you have low false positives and low false negatives.
- An F1 score is considered perfect when it's 1, while the model is a total failure when it's 0.

$$F_1 = 2 * \frac{precision * recall}{precision + recall}$$

Accuracy:

$$ACC = \frac{TP + TN}{TP + TN + FP + FN}$$

Recall:

$$Recall = \frac{TP}{TP + FN}$$

Precision:

$$Precision = \frac{TP}{TP + FP}$$

F<sub>1</sub> score:

$$F_1 = \frac{2}{\frac{1}{Recall} + \frac{1}{Precision}}$$

# Evaluating Model Performance (F-1 Score)

# Evaluating Model Performance (F-beta Score)

## F-beta Score

---

- Generalization of F-Score where beta is a parameter to weight the result of the precision or recall.
- Beta = 0.5 to focus more on precision, It's called F-0.5 Score.
- Beta = 2 to focus more on recall, It's called F-2 Score.
- Beta value should be used depending on your domain knowledge business case.

$$F_{\beta} = (1 + \beta^2) \cdot \frac{\text{precision} \cdot \text{recall}}{(\beta^2 \cdot \text{precision}) + \text{recall}}.$$

# Evaluating Model Performance (F-beta Score)

```
1 from sklearn.metrics import fbeta_score
2
3
4 fbeta_score(y_true, y_pred, beta=0.5)
5
6 """
7 0.9090909090909091

# Clustering

Clustering is the task of dividing the population or data points into a number of groups such that data points in the same groups are more similar to other data points in the same group and dissimilar to the data points in other groups.

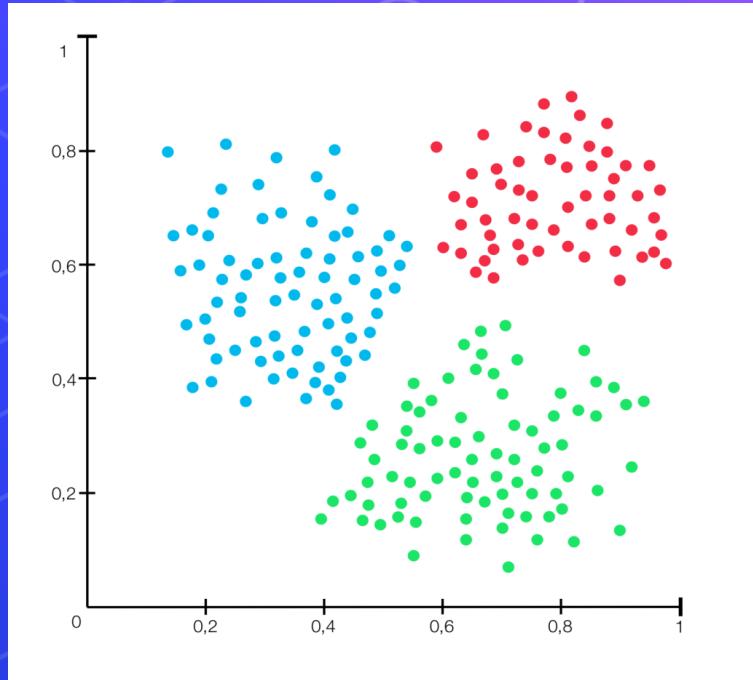

For example,  
it can be used to cluster the university students to many segments depending on features like scores, departments, etc.

- University students clustering
- Mall customers segmentation
- Recommendation systems
- ...

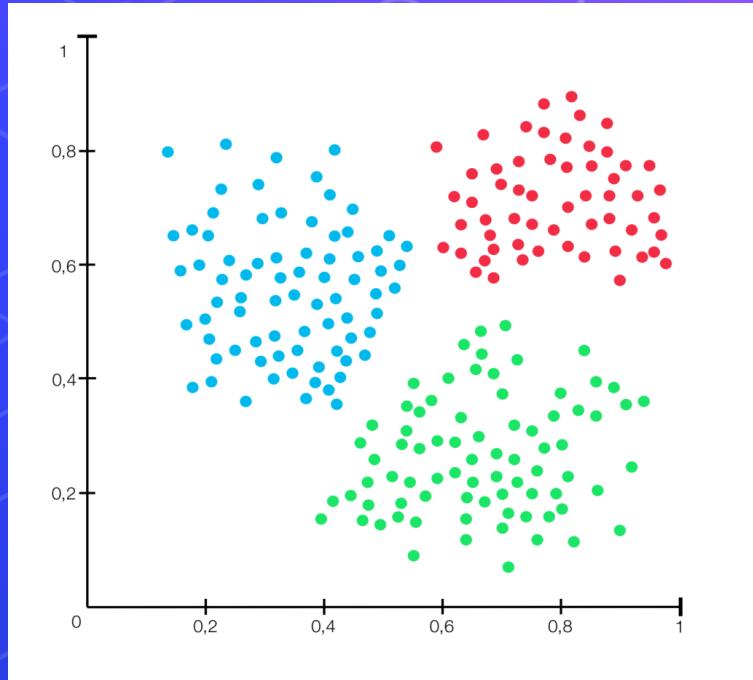

# Clustering

- KMeans
- Hierarchical Clustering
- Density Based Clustering – DBSCAN

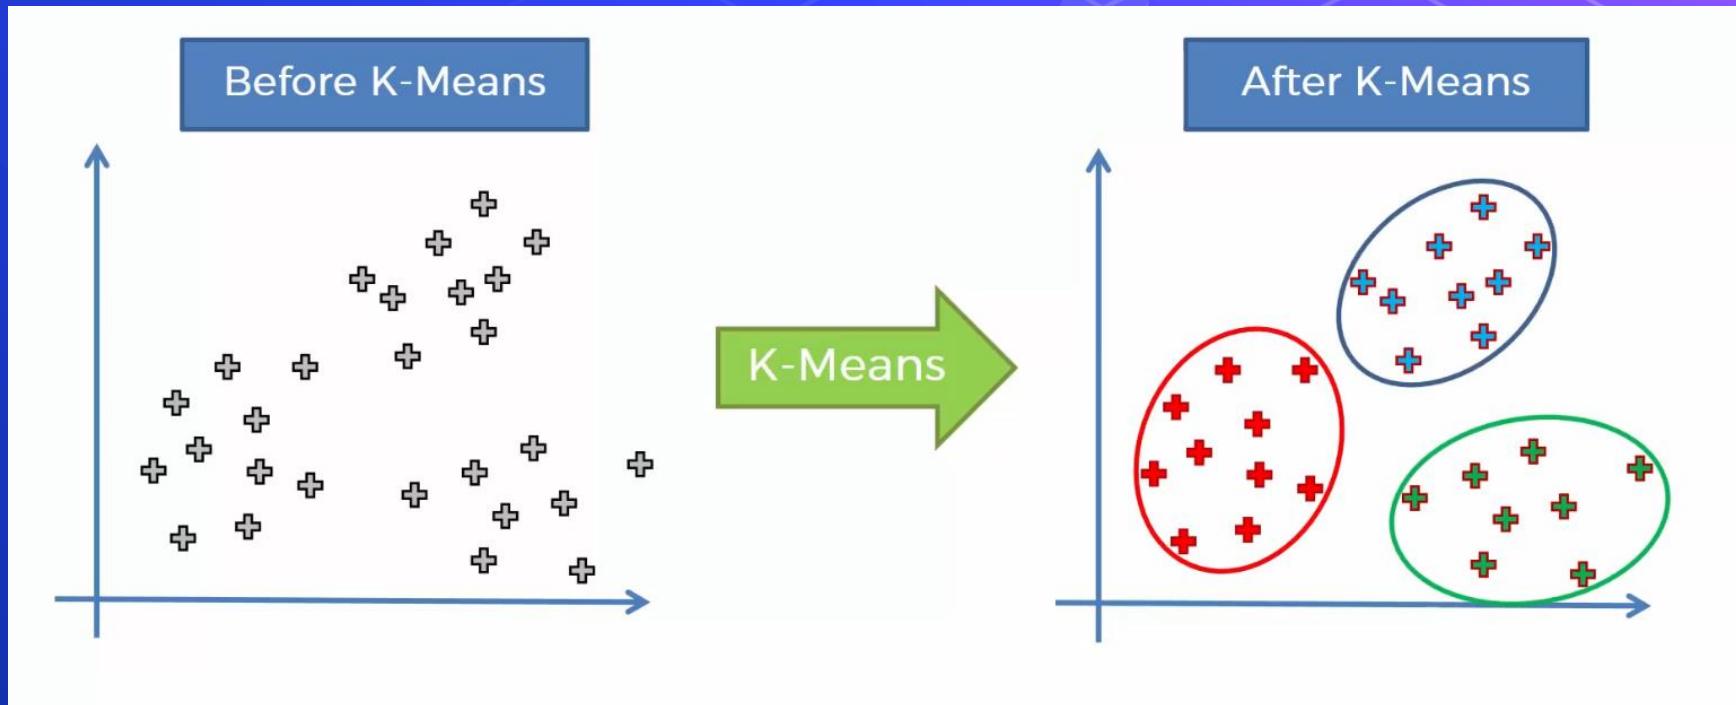

# Clustering

- KMeans
- Hierarchical Clustering
- Density Based Clustering – DBSCAN

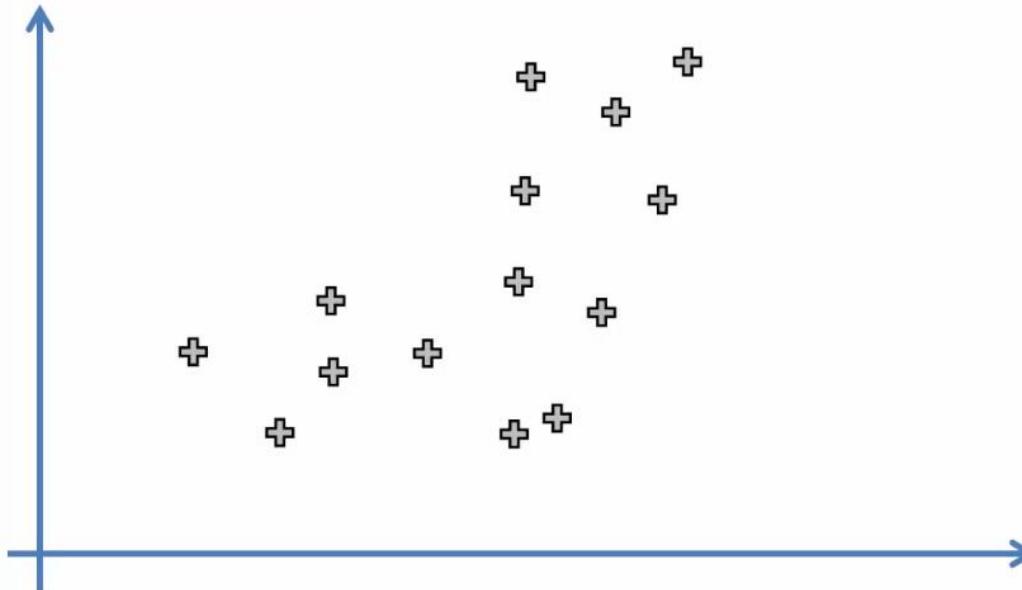

# KMeans

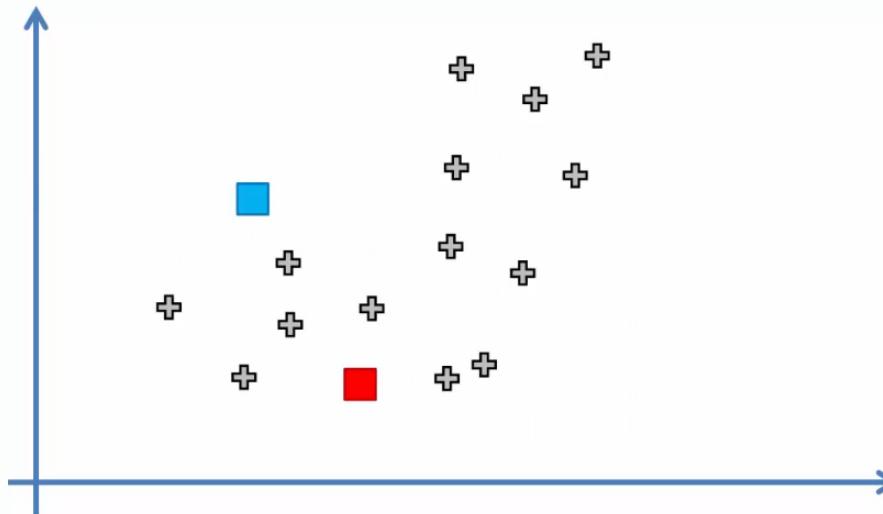

# KMeans

STEP 1: Choose the number K of clusters: K = 2

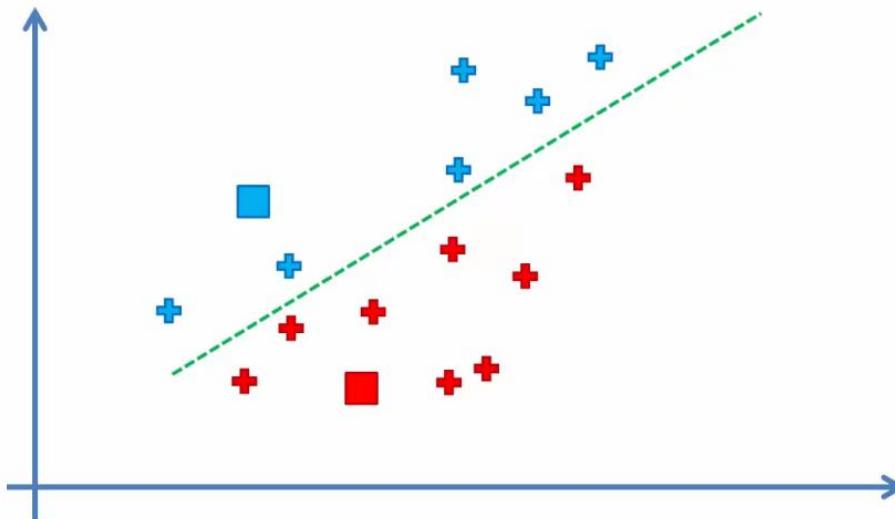

# KMeans

STEP 2: Select at random K points, the centroids (not necessarily from your dataset)

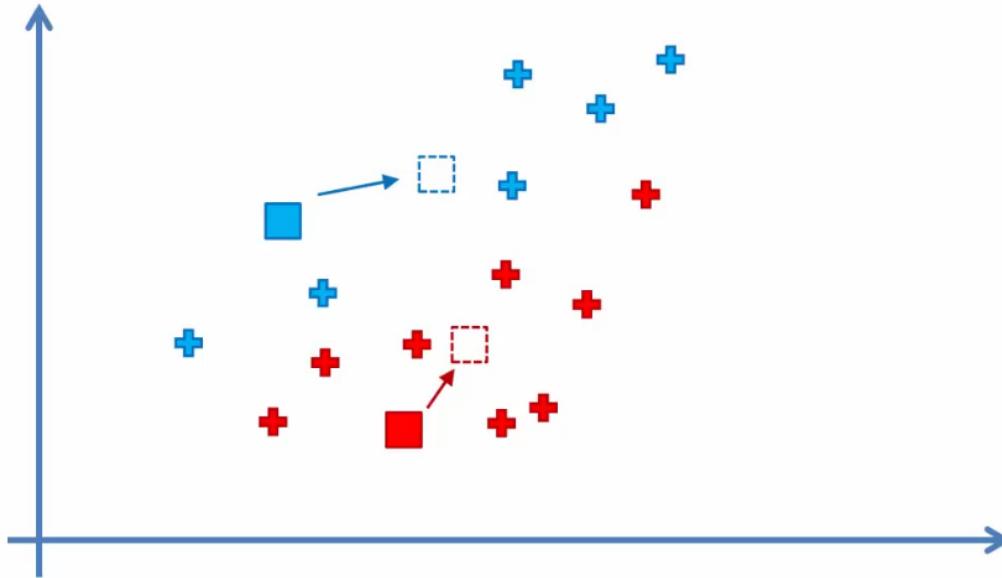

# KMeans

STEP 3: Assign each data point to the closest centroid → That forms K clusters

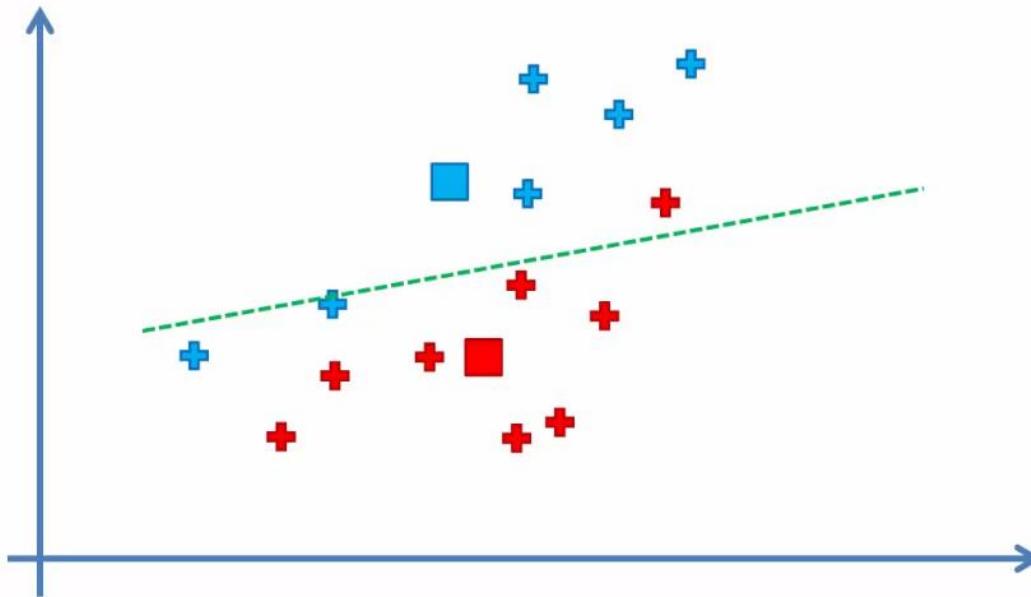

# KMeans

STEP 4: Compute and place the new centroid of each cluster

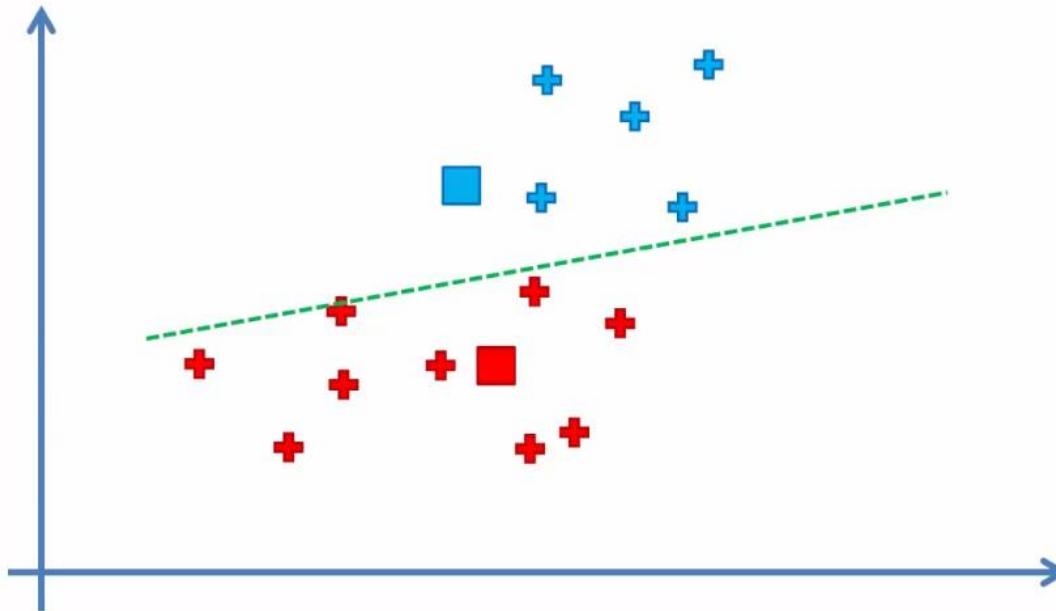

# KMeans

STEP 5: Reassign each data point to the new closest centroid.  
If any reassignment took place, go to STEP 4, otherwise go to FIN.

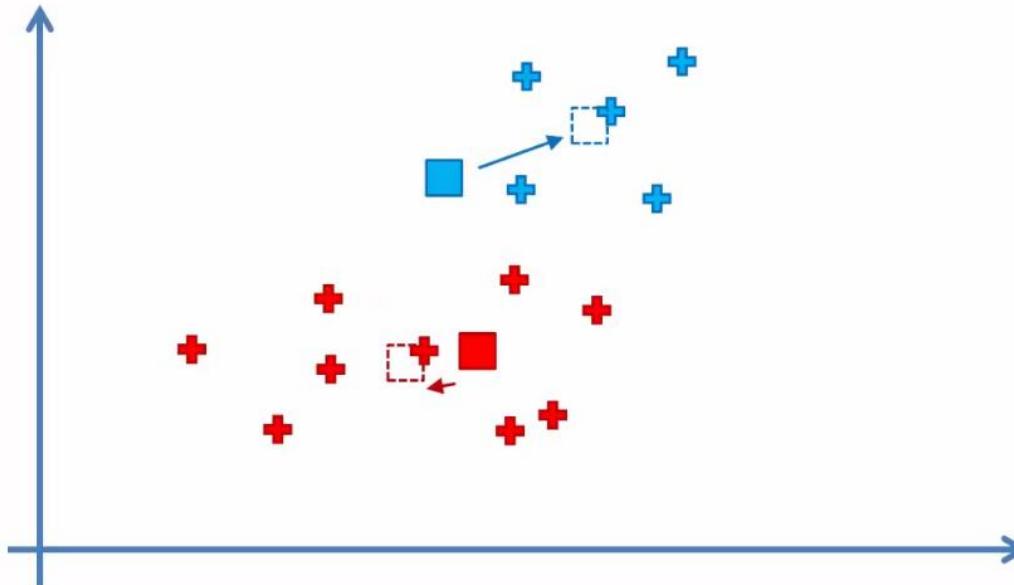

# KMeans

STEP 5: Reassign each data point to the new closest centroid.  
If any reassignment took place, go to STEP 4, otherwise go to FIN.

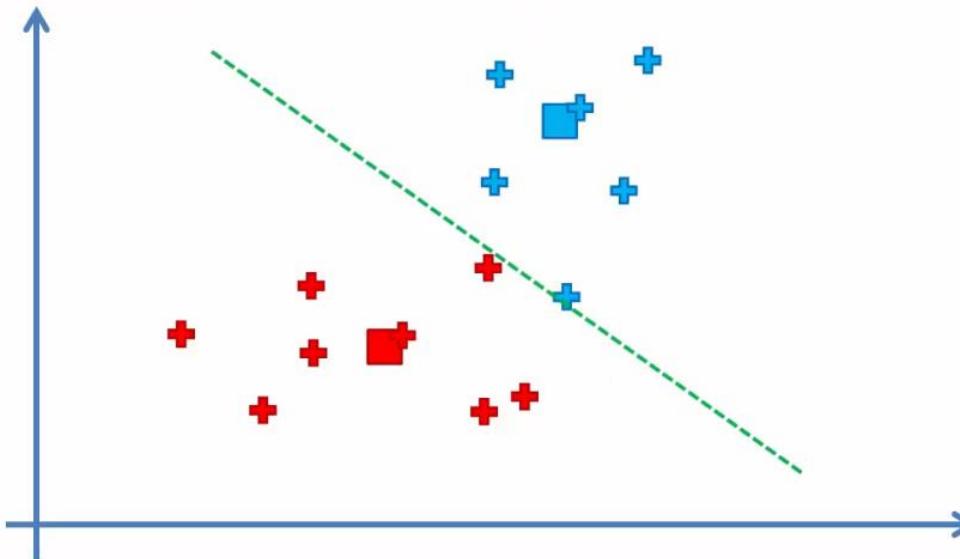

# KMeans

STEP 4: Compute and place the new centroid of each cluster

# KMeans

STEP 5: Reassign each data point to the new closest centroid.  
If any reassignment took place, go to STEP 4, otherwise go to FIN.

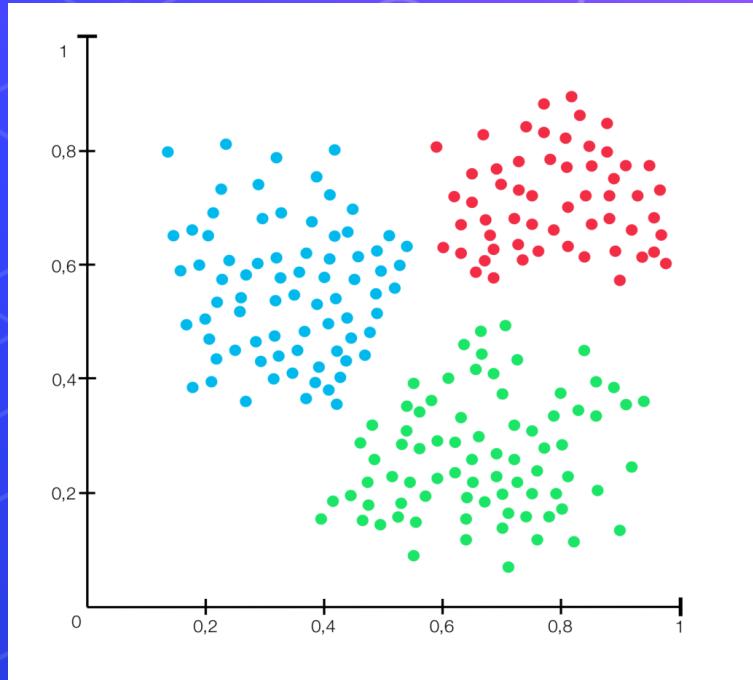

# KMeans

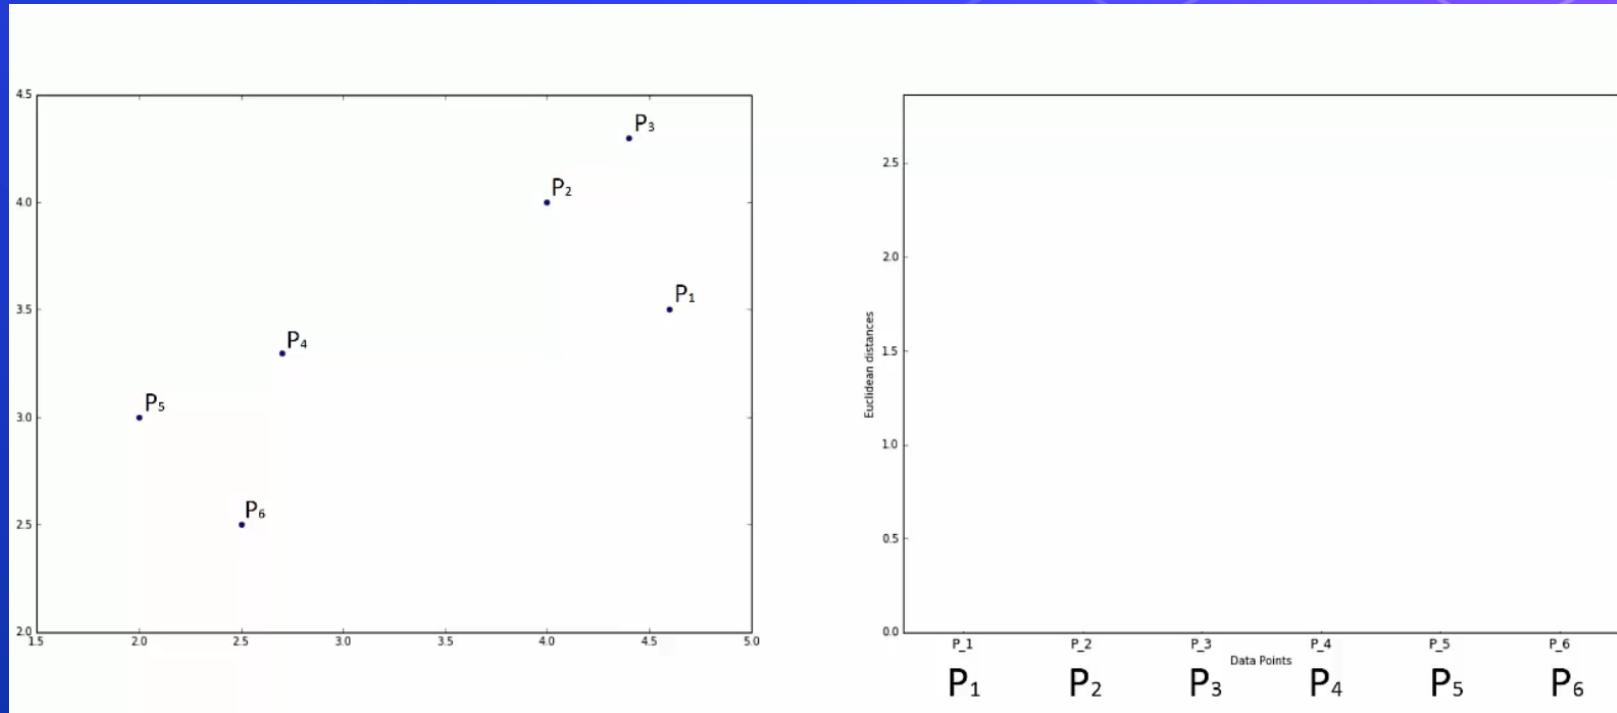

```
1 from sklearn.cluster import KMeans  
2  
3 kmeans = KMeans(n_clusters=3)  
4 kmeans.fit(X)  
5 kmeans.predict(X)
```

# Dimension Reduction

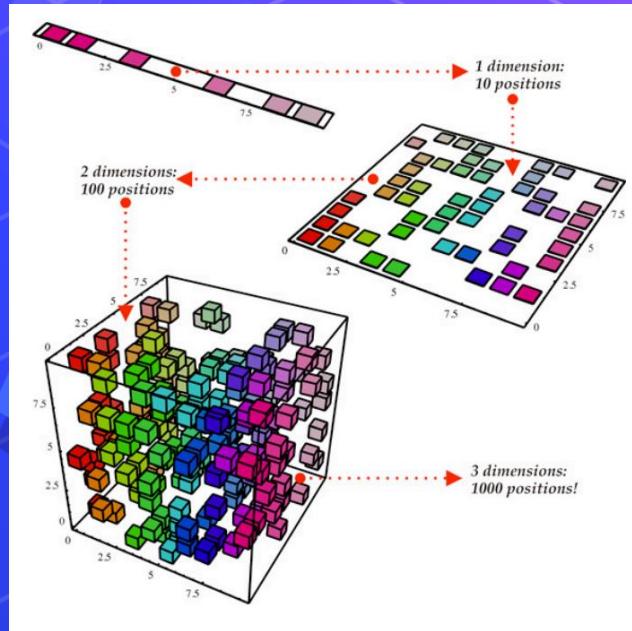

is the transformation of data from a high-dimensional space into a low-dimensional space so that the low-dimensional representation retains some meaningful properties of the original data

For example,  
it can be used as data compression to reduce size of data for  
easy processing.

# Dimension Reduction

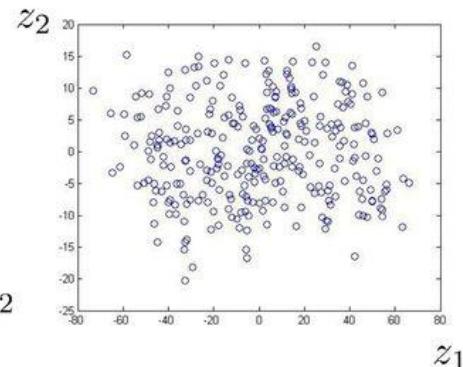

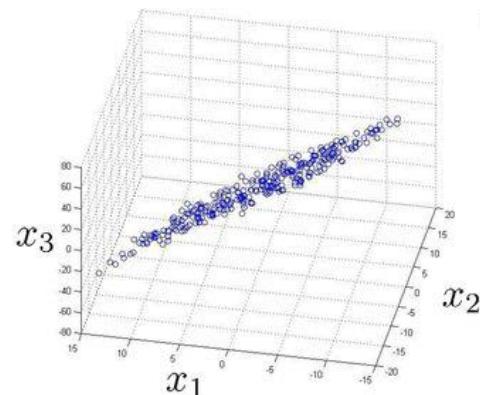

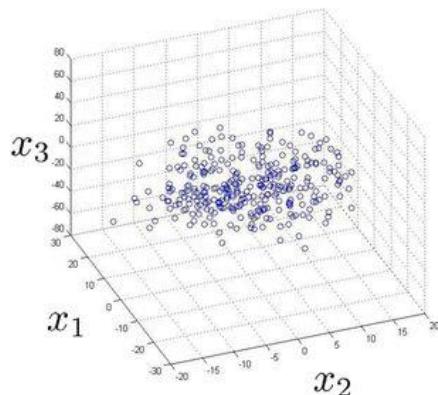

○ PCA

# PCA

## Data Compression

Reduce data from 3D to 2D

Andrew Ng

# PCA

```
1 from sklearn.decomposition import PCA  
2  
3 X = # feature vector  
4  
5 pca = PCA(0.9)  
6 X = pca.fit_transform(X)  
7 pca.explained_variance_ratio_
```

# PCA

## PRINCIPAL COMPONENT ANALYSIS

PCA projects the features onto the principal components. The motivation is to reduce the features dimensionality while only losing a small amount of information.

The diagram illustrates the process of projecting data points onto principal components. The first principal component is a straight line that captures the maximum variance of the data, while the second principal component is a curved line that captures the remaining variance.

[https://en.wikipedia.org/wiki/Principal\\_component\\_analysis](https://en.wikipedia.org/wiki/Principal_component_analysis)

# Cross Validation with K-Fold

## Why we use Cross Validation

- Cross Validation uses **Stratified** technique to make sure the distribution of the categorical target is the same in every fold.
- More “efficient” use of data as every observation is used for both training and testing.
- Reduce overfitting and the model achieve the generalization.

# Cross Validation with K-Fold

# Cross Validation with K-Fold

```
1 from sklearn.svm import SVC
2 from sklearn.model_selection import cross_validate
3
4 svc = SVC()
5 cv_results_svc = cross_validate(svc, X, Y, cv=10, return_train_score=True)
6
7 cv_results_svc['test_score'].mean()
8 """
9 0.8036085674097743
10 """

# What is Deep Learning

# What is Deep Learning

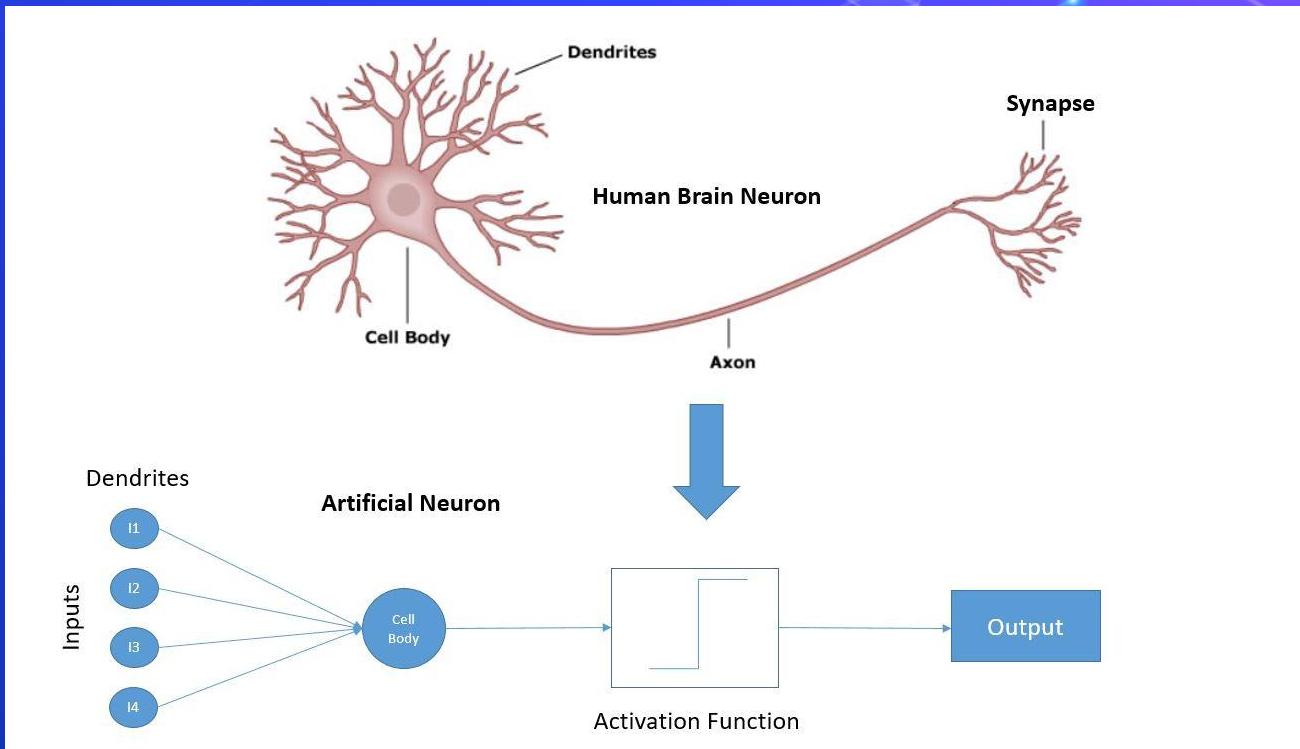

Traditional machine learning uses hand-crafted features, which is tedious and costly to develop.

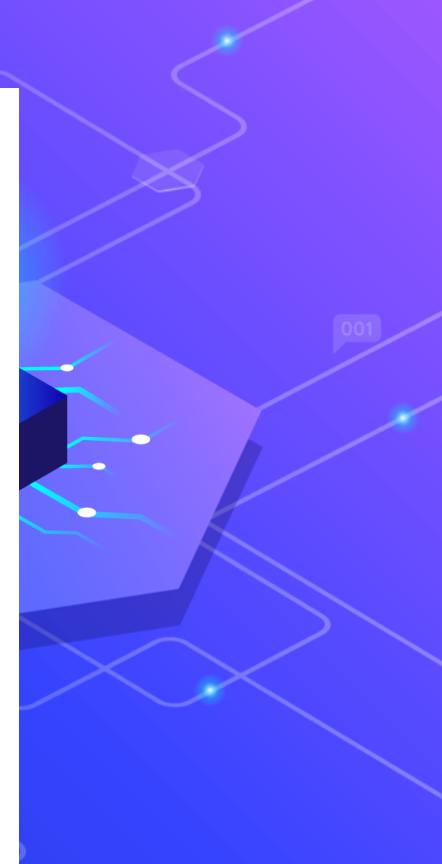

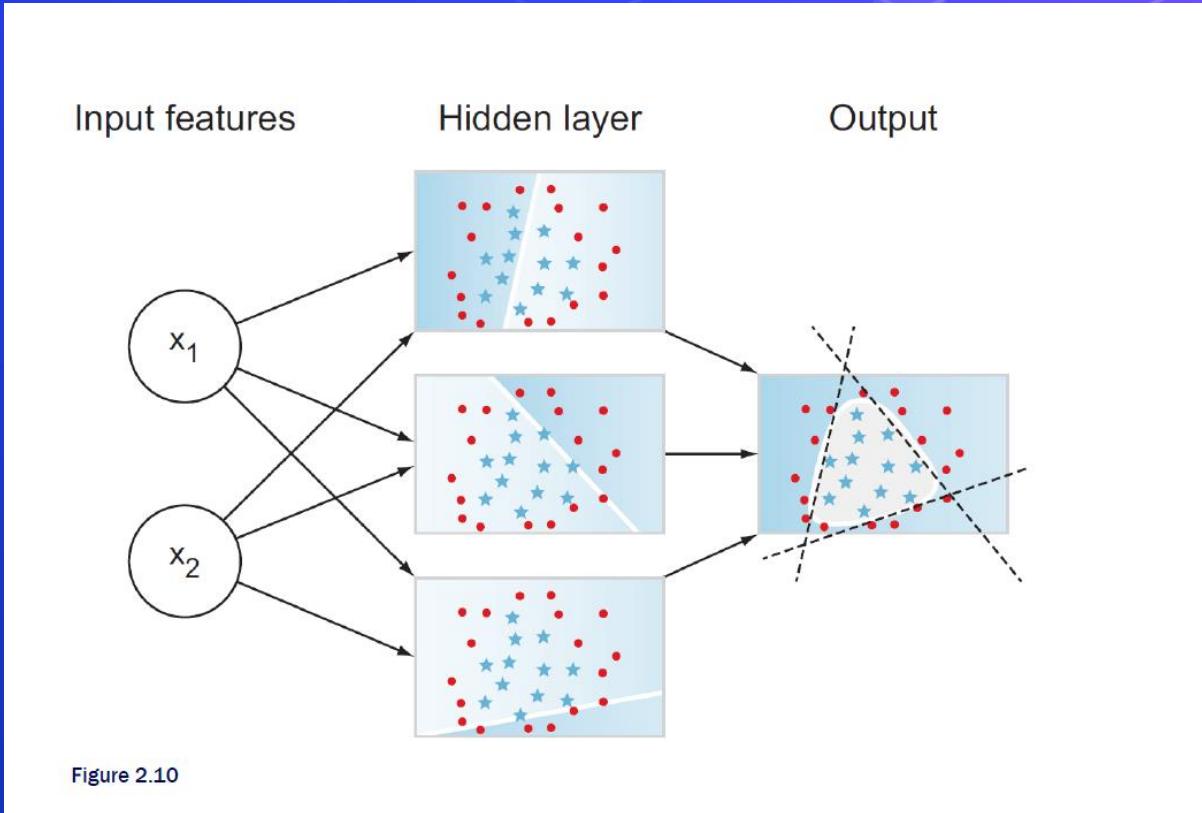

Deep learning learns hierarchical representation from the data itself, and scales with more data.

Salit Kulla  
to me

11:29 AM \*\*\*

Hey, Wynton Marsalis is playing this weekend. Do you have a preference between Saturday and Sunday?

-S

I'm down for either.

Let's do Saturday.

I'm fine with whatever.
